## (Received 29 August 1995)

Key Word Index-Eriosema tuberosum; Leguminosae; roots; chromones; antifungal activity.

Abstract—Four new prenylated chromones have been isolated from a dichloromethane extract of the roots of *Eriosema tuberosum*. Their structures were elucidated by spectroscopic methods. Eriosematin A exhibited antifungal activity against *Cladosporium cucumerinum* and *Candida albicans* in TLC bioautographic assays.

#### INTRODUCTION

In the course of our studies on the secondary metabolites of the Chinese plant *Eriosema tuberosum*, nine phenolic compounds were described in a previous paper [1]. Continuation of this work on the antifungal metabolites of this species has led to the characterization of a further four new prenylated chromones from a dichloromethane extract of the roots. The structural elucidation and antifungal activities of these compounds are reported.

#### **RESULTS AND DISCUSSION**

Compound 1, obtained as yellow powder, had a molecular formula of C<sub>19</sub>H<sub>20</sub>O<sub>4</sub> based on TSP- and EImass spectra and <sup>13</sup>C NMR spectral data. The <sup>1</sup>H NMR spectrum revealed clearly the presence of an isoprenyl group [ $\delta$ 1.67, 1.79 (2 × Me) , 3.32 (1 × CH<sub>2</sub>) and 5.21  $(1 \times CH)$ ] and a chelated hydroxyl group ( $\delta$ 12.86). The remaining proton signals were assigned to a dimethylchromene ring [( $\delta$ 1.45 (2 × Me), 6.65 and 5.57 (J = 10 Hz)] and an  $\alpha$ ,  $\beta$  -unsaturated ketone moiety [ $\delta$ 7.74 and 6.18 (J = 6 Hz)]. These findings were quite similar to the <sup>1</sup>H NMR data (Table 1) or eriosematin [1]. However, careful comparison of the chemical shift of the chelated proton in 1 and eriosematin ( $\delta$ 12.86 for 1 and 12.78 for eriosematin) suggested that the dimethylchromene ring was fused at the C-7 and C-8 positions on the A ring of 1 instead of C-6 and C-7 in eriosematin [2,3]. The <sup>13</sup>CNMR data (Table 2) of 1 showed that it has an angular fusion pattern of the dimethylchromene ring on the A ring because the signals of C-5, C-6, C-8 and C-9 were different from those of eriosematin. This angular fusion pattern of 1 was finally confirmed by the long-range coupling observed in a FLOCK experiment (Fig. 1) [4]. Thus, compound 1 was characterized as 5-hydroxy-6- $\gamma$ , $\gamma$ -dimethylallyl-6',6'-dimethyl-pyrano (2', 3': 7, 8) chromone, named iso-eriosematin.

Compound 2, obtained as yellow powder, possessed a molecular formula of  $C_{14}H_{14}O_4$ , as deduced from the EI-mass spectrum and analysis of <sup>13</sup>CNMR spectral data (Table 2). In the <sup>1</sup>H NMR spectrum of 2, a set of signals characteristic of an isoprenyl group [ $\delta$ 1.73, 1.81  $(2 \times Me)$ , 3.45  $(1 \times CH_2)$  and 5.21  $(1 \times CH)$ ] was unambiguously assigned. Moreover, the presence of two olefinic protons resonating at  $\delta$ 7.80 (J = 6 Hz) and 6.22 (J = 6 Hz) and a chelated hydroxyl group ( $\delta 12.51$ ) suggested that 2 was a chromone. However, the absence of the proton signals for a dimethylchromene ring, which were replaced by one proton at  $\delta 6.32$ , indicated that 2 was not completely substituted on the A ring. This assumption was subsequently confirmed by the <sup>13</sup>CNMR spectrum and DEPT of 2, which provided a total of 14 resonance lines consisting of two methyl, one methylene, four methine and seven quaternary carbons. Comparison of these data, especially the signal resonating at  $\delta$ 99.8, with those of heteroflavanones B and C, leachianones F and G, 2-hydroxymethlalloptaeroxylins 1 and 2 [3, 5-7] revealed that C-5 and C-7 were substituted by a hydroxyl group, with C-8 prenylated. Thus, the structure of compound 2 was established as 5,7-dihydroxy-8- $\gamma$ , $\gamma$ -dimethylallyl chromone, named eriosematin A.

The molecular formula of compound 3 was found to be  $C_{19}H_{24}O_5$ , by EI-mass ([M]<sup>+</sup> at m/z 332) and <sup>13</sup>C NMR spectral data (Table 2). The <sup>1</sup>H NMR spectrum showed some common signals similar to those of compound 2. Moreover, the occurrence of a six-proton singlet at  $\delta 1.29$  and a pair of two-proton triplets (J = 6 Hz) at  $\delta 1.78$  and  $\delta 2.77$  indicated the presence of a 3-hydroxy-3,3-dimethylbutyl group. The EI-mass spectrum revealed

Fig. 1. Long-range couplings between protons and carbons deduced from the FLOCK NMR spectrum of compound 1.

that the  $[M]^+$  was fragmented through a process of water loss from the parent ion followed by successive eliminations of two  $\gamma,\gamma$ -dimethylallyl groups. Loss of 55 (C<sub>4</sub>H<sub>8</sub>) in the cleavage pathway A (Fig. 2) suggested that the C-6 position was substituted by one  $\gamma,\gamma$ -dimethylallyl group and the cleavage pathway B indicated that the C-8 position was connected with another  $\gamma,\gamma$ -dimethylallyl group [8,9]. After comparing the <sup>1</sup>H and <sup>13</sup>C NMR spectral data of **3** with those of analogues [10,11], the presence of a 3-hydroxy-3,3-dimethylbutyl group could be ascertained. The long-range couplings observed in a FLOCK experiment (Fig. 3) finally confirmed that the C-6 position was connected with the 3-hydroxy-3,3dimethylbutyl group. Therefore, the structure of **3** was

established as 5,7-dihydroxy-6-(3-hydroxy-3,3-dimethylbutyl)-8- $\gamma$ , $\gamma$ -dimethylallyl chromone, named eriosematin B.

Compound 4 had a molecular formula  $C_{19}H_{22}O_4$ , as deduced from the EI-mass spectrum ([M]<sup>+</sup> at m/2 314, 18 amu lower than that of compound 3) and <sup>1</sup>H NMR spectral data (Table 1). The <sup>1</sup>H NMR spectrum demonstrated the presence of two  $\gamma$ , $\gamma$ -dimethylallyl groups and a chelated hydroxyl group. The EI-mass data were similar to those of compound 3, but the fragment produced by loss of water from the [M]<sup>+</sup> could not be seen. These findings could only be explained by assuming that compound 4 was a dehydrated derivative of compound 3. Therefore, the structure of 4 was characterized as 5,7dihydroxy-6- $\gamma$ , $\gamma$ -dimethylallyl-8- $\gamma$ , $\gamma$ -dimethylallyl chromone, named eriosematin C.

Despite their rather simple structures, the four chromones isolated from the lipophilic root extract of *E. tuberosum* are new natural compounds. All four chromones were evaluated for their antifungal activities against *Cladosporium cucumerinum* and *Candida albicans* according to established methods [12,13]. Compared with miconazole (activity against *C. albicans* is 0.01  $\mu$ g) and propiconazole (activity against *C. cucumerium* is 0.001  $\mu$ g) the minimal amount of compound 2 needed to inhibit fungal growth on TLC plates was 2.5  $\mu$ g for both fungi; the other three compounds were not active. It appears that prenylation at the C-6 position reduces antifungal activities significantly.

#### **EXPERIMENTAL**

Details of instruments and chromatographic conditions used in this work were essentially the same as described in ref. [1].

Plant material. Roots of E. tuberosum (1.67 kg) were collected in June 1992 in Fu Ming County, Yunnan Province, P. R. China. A voucher specimen is deposited in the Herbarium of Kunming Institute of Botany, Chinese Academy of Science.

*Extraction and isolation.* Powdered roots were extracted at room temp. successively with CH<sub>2</sub>Cl<sub>2</sub> and MeOH.

Fig. 2. Mass spectral fragmentations of compound 3 showing different possible cleavage pathways.

The CH<sub>2</sub>Cl<sub>2</sub> extract (120 g) was submitted to CC on silica gel (40–63  $\mu$ m, 2000 g) using step-gradient elution (*n*-hexane-EtOAc, 9:1 to 0:100); 15 frs (A–O) were collected. Fr. H (4 g) was chromatographed by MPLC on a Diol column (*n*-hexane-EtOAc, 4:1) yielding 5 frs. Fr. 3 was submitted to semi-prep. HPLC on RP-18 (MeOH-H<sub>2</sub>O, 7:3) to give compounds 2 (15 mg) and 3 (6.6 mg). Fr. G (2 g) was submitted to CC on silica gel eluted with *n*-hexane-EtOAc (2:1) giving three frs a–c.

Fr. a was chromatographed by semi-prep. HPLC on RP-18 (MeOH $-H_2O$ , 7:3) to give compounds 1 (14 mg) and 4 (1 mg).

Compound 1 [5-hydroxy-6- $\gamma$ , $\gamma$ -dimethylallyl-6',6'-dimethyl -pyrano (2', 3': 7, 8) chromone, iso-eriosematin]. Yellow powder, mp 97–101°.
