Abstract

In this study, we report a complete mitochondrial (mt) genome sequence of the Texel ewe, *Ovis aries*. The total genome is 16,615 bp in length and its overall base composition was estimated to be 33.68% for A, 27.36% for T, 25.86% for C, and 13.10% for G indicating an AT-rich (61.04%) feature in the *O. aries* mtgenome. It contains a total of 13 protein-coding genes, 22 transfer RNA genes, 2 ribosomal RNA genes and a control region (D-loop region). Comparisons with other publicly available sheep mitogenomes revealed a bunch of nucleotide diversity. This complete mitogenome sequence would enlarge useful genomic information for further studies on sheep evolution and domestication that will enhance germplasm conservation and breeding programs of *O. aries*.

Keywords

Comparative mitochondrial genomics, *Ovis aries*, Texel ewe

Domesticated sheep, *Ovis aries*, have had an important part in human settlement, providing a farmed source of food, wool and hide since the Neolithic Agricultural revolution approximately 8000–9000 years ago (Ryder, 1984). Mitochondrial genome has long been recognized as an important organelle related to disease, apoptosis, aging and metabolism (Boore, 1999). The complete mitochondrial (mt) genome sequencing and analyses of a number of haplotype groups identified in domestic sheep and its wild relatives have given in-depth insights into the sheep mtgenome-wide variation and their evolutionary relationships (Hiendleder et al., 1998; Hiendleder, 1998; Lancioni et al., 2013; Meadows et al., 2011; Miller et al., 2012). These obtained findings indicate that more representatives of sheep reference mtgenomes would better provide evidence of its origins and domestication and further enhance the germplasm conservation and breeding programs. Here, using the Velvet package (Zerbino & Birney, 2008), we assembled and characterized the complete mitochondrial genome of the Texel ewe, *O. aries*, with the Illumina sequencing dataset released by Jiang et al. (2014). This mitochondrial sequence will enlarge genomic resources of a global sheep reference mtgenome panel that would greatly help germplasm conservation and utilization of *O. aries*.

The complete mitochondrial genome (GenBank Accession Number: KJ954145) of *O. aries* (16,615 bp in length) harbored a

total 13 protein-coding genes, 22 tRNA genes, 2 rRNA genes and two non-coding regions: the origin of light-strand replication (*OL*) and control region (*D-loop*) (Table 1). The total base compositions are 33.68% A, 27.36% T, 25.86% C, and 13.10% G; the percentage of A + T (61.04%) was found to be higher than G + C (38.96%). Most of these genes are encoded on the H-strand, except for the *ND6* gene and 8 tRNA genes that are encoded on the L-strand. All protein-coding genes are 11,373 bp in length, which together encode 3805 amino acids. A total of 13 open reading frames of protein-coding sequences have the typical ATN initiation codon. Seven genes used TAA as their termination codon, whereas *ND2* and *Cyt b* use with TAG and AGA, respectively. In addition, there are four genes (*COX3*, *ND3*, *ND4* and *ND6*) that were found with an incomplete stop codon.

The mitogenome of *O. aries* contains a small subunit of 12S rRNA (958 bp), a large subunit of 16S rRNA (1574 bp) and a typical set of 22 tRNA genes. These ribosomal subunit genes are located between the *tRNA-Phe* and *tRNA-Leu* genes and further separated by the *tRNA-Val* gene. The total length of all tRNAs is 1510 bp, varying from 64 bp (*tRNA-phe*) to 75 bp (*tRNA-Leu*). The *OL* is 32 bp in length, which is located between *tRNA-Asn* and *tRNA-Cys* genes within the WANCY cluster (*tRNA-Asn*, *tRNA-Cys*, *tRNA-Trp*, *tRNA-Ala* and *tRNA-Tyr*). The control region (CR) or *D-loop* is 1180 bp in length and is positioned between *tRNA-Pro* and *tRNA-Phe*.

We next compared the complete Texel ewe mitochondrial genome with seven *O. aries* breeds and three *Ovis* species (*O. vignei*, *O. ammon* and *O. canadensis*) (Hiendleder et al., 1998; Hiendleder, 1998; Lancioni et al., 2013; Meadows et al., 2011; Miller et al., 2012) (Table 1). Our results show that the gene order and base composition were expectedly conserved one another; however, SNPs and genome sizes varied slightly within *O. aries* but higher levels of variation were detected among different *Ovis* species.
