Keywords: Rauvolfia verticillata Monoterpenoid indole alkaloid Rauvovertine Cytotoxicity

1. Introduction

Plants of the genus Rauvolfia (Apocynaceae), comprising approximately 60 species, are trees or shrubs mainly distributed in America, Africa, Asia, and Oceania, of which seven species are present in China [1]. Rauvolfia verticillata is a prolific source of heterocyclic indole alkaloids, and also an indigenous medicinal plant used in China to treat snake poisoning, hypertension, malaria, insanity, and typhus [1, 2]. As part of a BioBioPha [http://www.chemlib.cn] objective to assemble a large-scale natural product library valuable in the discovery of new drug leads from nature [3,4], phytochemical investigation on the stems of *R. verticillata* led to the isolation of five new hexacvclic monoterpenoid indole alkaloids, rauvovertine A (1), 17-epirauvovertine A (2), rauvovertine B (3), 17-epi-rauvovertine B (4), and rauvovertine C (5) (Fig. 1), together with 17 known analogues, peraksine [5], vellosimine [6], tombozine [6], 3-hydroxysarpagine [7], macusine B [8], dihydroperaksine [9], sarpagine [10], spegatrine [11], akuammidine [12], 10-hydroxy-16-epiaffinine [13], pelerine [14], β yohimbine [15], α -yohimbine [15], antirhine [16], strictosamide [17], sitsirikine [18], and reserpine [19]. The present paper describes the isolation and structure elucidation of the new alkaloids 1-5, and their cytotoxic evaluation against HL-60, SMMC-7721, A-549, MCF-7, and SW-480 cell lines.

2. Results and discussion

human tumor HL-60, SMMC-7721, A-549, MCF-7, and SW-480 cell lines.

Five new hexacyclic monoterpenoid indole alkaloids, rauvovertine A (1), 17-epi-rauvovertine A (2), rauvovertine

B (3), 17-epi-rauvovertine B (4), and rauvovertine C (5) together with 17 known analogues were isolated from

the stems of Rauvolfia verticillata. Compounds 1/2 and 3/4 were obtained as C-17 epimeric mixtures due to

rapid hemiacetal tautomerism in solution. The structures of 1-5 were established by spectroscopic analysis

and with the aid of molecular modeling. The new alkaloids were evaluated for their cytotoxicity in vitro against

Compound 1/2 was isolated as an inseparable C-17 epimeric mixture (3:2) where some of the signals appeared as duplicate in the NMR spectra (Tables 1 and 2). Its molecular formula was determined as $C_{19}H_{22}N_2O_3$ from HREIMS at m/z 326.1628 [M]⁺ (calcd 326.1630), requiring 10 degrees of unsaturation. The IR spectrum suggested the presence of OH/NH (3421 cm⁻¹) functionalities. The UV spectrum showed absorptions at λ_{max} 222, 277 and 288 nm typical of an unsubstituted indole chromophore [20]. The ¹H NMR spectrum (Table 1) displayed one NH group at $\delta_{\rm H}$ 10.72/10.74 (1H, s), two active hydroxy protons at $\delta_{\rm H}$ 6.49/6.09 (1H, d, I = 4.0/3.5 Hz) and 5.74 (1H, br s), four aromatic protons at $\delta_{\rm H}$ 7.33/7.32 (1H, d, J = 7.1 Hz), 7.24/7.25 (1H, d, J = 8.0 Hz), 6.98 (1H, t-like, I = 7.5 Hz), and 6.90/6.91 (1H, t-like, I = 7.4 Hz), and one secondary methyl at $\delta_{\rm H}$ 1.14/1.08 (3H, d, I = 6.6 Hz). The ¹³C NMR and DEPT spectrum (Table 2) exhibited 19 carbon signals of each epimer, consisting of one methyl, two sp³ methylenes, eight sp³ methines, four sp² methines, and four sp² quaternary carbons. Combined analysis of its ¹H and ¹³C NMR data indicated that 1/2 had a framework of sarpagine-type alkaloid [21]. The signals assignable to a hemiacetal methine ($\delta_{\rm H}$ 4.55/4.82; $\delta_{\rm C}$ 96.83/93.76) and an oxygenated methine ($\delta_{\rm H}$ 3.49/4.02; $\delta_{\rm C}$ 71.08/65.35) suggested the presence of 17,19-epoxy moiety, which was further confirmed by the HMBC correlation from H-17 to C-19 (Fig. 2). And the HMBC correlations from H-17 to C-5, C-15 and C-19, and from H-21 to C-3 and C-19 permitted the assignment of hydroxy groups at C-17 and C-21, respectively.

The relative configuration of each epimer was established spectroscopically based on computer-generated 3D drawing with minimized energy by MM2 calculation (Fig. 3). In the ROESY spectrum of **1**/**2**, the correlation of H-16 \leftrightarrow H-6 β demonstrated that H-16 and H-6 β were in

Fig. 1. The structures of compounds 1-5.

the same side, and the correlations of H-21 \leftrightarrow H-5/Me-18, 21-OH \leftrightarrow H-3, and H-20 \leftrightarrow H-14 α revealed the α -orientation of H-3, H-5, H-20, 21-OH and Me-18. The hemiacetal methine proton H-17 showed the significant ROESY correlations with H-15/H-19 in 1, but with H-5, not H-15/ H-19 in 2 (Fig. 3), which revealed that the orientations of H-17 were assigned as β in **1** and α in **2**. Another noteworthy observation is that the chemical shift of H-5 ($\delta_{\rm H}$ 3.22) in **1** was relatively deshielded compared to that of H-5 ($\delta_{\rm H}$ 2.87) in **2**, while the shifts of H-15 ($\delta_{\rm H}$ 2.00) and H-19 ($\delta_{\rm H}$ 4.02) in **2** were relatively deshielded compared to those of H-15 (δ_H 1.52) and H-19 (δ_H 3.49) in **1**, which is attributed to paramagnetic deshielding effects caused by the hemiacetal hydroxy group. Conformationally, the pyran ring in this mixture (1:2 \approx 3:2) adopted a chair form, in which 17α -OH in the major epimer occupied an equatorial position. As a result, the major epimer is lower in energy

and more is present at the equilibrium since a molecule favors the conformation in which larger substituent is in equatorial position. Hence, the structures of 1/2 were unambiguously established as 17,19-epoxy-19,20-dihydrosarpagane- $17\alpha/\beta$,21 α -diol, and given the trivial names rauvovertine A and 17-epi-rauvovertine A, respectively.

Compound 3/4 was also isolated as an inseparable C-17 epimeric mixture (\approx 2:1) with the same molecular formula as 1/2, determined by HREIMS at m/z 326.1638 [M]⁺ (calcd for C₁₉H₂₂N₂O₃, 326.1630). The NMR data (Tables 1 and 2) of 3/4 were very similar to those of peraksine [5], but it was evident that **3**/**4** had an additional hydroxy group located at C-10 since the methine signal of C-10 in peraksine was changed to an oxygenated quaternary carbon ($\delta_{\rm C}$ 152.04) in **3/4**, which was confirmed by the HMBC correlation from the *m*-coupled broad singlet of H-9 to C-7 and the ROESY correlation of H-9 \leftrightarrow H-6 β . The relative configuration of 3/4 was established on the basis of its ROESY spectrum. The correlations of H-16 \leftrightarrow H-6 β , H-3 \leftrightarrow H-19 and

Fig. 2. Key HMBC correlations of 1/2.

Me-18 \leftrightarrow H-5 indicated that these protons were spatially close to each other. Similarly, the orientation of H-17 was assigned as β in **3** and α in **4** according to the presence/absence of ROESY correlations of H-17 \leftrightarrow H-15/H-21 β and H-17 \leftrightarrow H-5. This was also verified by the 17-OH induced downfield shifts for H-5 (Δ = 0.18 ppm) in **3** and H-15 (Δ = 0.50 ppm) and H-21 β (Δ = 0.49 ppm) in **4** compared to their counterparts. Thus, the structures of **3**/4 were finally established as 17,19-epoxy-19,20-dihydro-21-methyl-18-norsarpagane-10,17 α / β -diol and named rauvovertine B and 17-*epi*-rauvovertine B, respectively.

Compound 5 gave a molecular formula of C₂₀H₂₃N₃O by HREIMS ([M]⁺ *m*/*z* 321.1849, calcd 321.1841). Comparison of its ¹³C NMR data (Table 2) with those of 3/4 revealed similarities except for the replacement of the hydroxy group at C-17 by a methoxy ($\delta_{\rm C}$ 56.64), and of the oxygenated methylene (δ_{C} 64.84/59.22) at C-21 by an unusual olefinic methine (δ_{C} 169.98). The location of the methoxy was established by the HMBC correlation from OMe ($\delta_{\rm H}$ 3.58) to C-17. Combined analysis of the NMR and MS information of 5 implied the presence of a rare imine group (δ_H 8.00; δ_C 169.98) between C-17 and C-20, confirmed by the HMBC correlations from H-21 to C-15. C-17 and C-20. The orientation of H-17 was assigned as β from the ROESY correlation of H- $17 \leftrightarrow$ H-15. Thus, the structure of **5** was elucidated as shown in Fig. 1 and named rauvovertine C. It represents a new class of peraksine alkaloid with an unusual N bridge between C-17 and C-20. A possible biosynthetic pathway for 5 was proposed as shown in Scheme 1. The key intermediate product 6 could be enzymatically synthesized from perakine [9], an alkaloid isolated previously from the genus Rauvolfia [2,9]. Intermediate product **7** was proposed to be generated from **6** through the amination reaction with the participation of β -aminoethanol [22,23].

Generally, the alkaloids **1–5** represent two types of carbon skeletons related to sarpagine and peraksine. Since the absolute stereochemistry of sarpagine and peraksine were assigned previously [24,25], biogenetically, the absolute stereochemistry of **1–5** could be assumed as (3*S*,5*S*,15*S*,16*R*,17*R*/*S*,19*R*,20*R*,21*R*) for **1/2**, (3*S*,5*S*,15*S*,16*R*,17*R*/*S*,19*S*,20*S*) for **3/4** and (3*S*,5*S*,15*S*,16*R*,17*S*,19*S*,20*S*) for **5**, as shown in Fig. 1.

All new alkaloids were evaluated for their in vitro growth inhibitory effects toward five human cancer cell lines with cisplatin and taxol as positive controls by the MTS method. The results showed that compound **5** exhibited moderate cytotoxicity against HL-60, SMMC-7721, A-549, MCF-7 and SW-480 with IC₅₀ values of 10.76, 15.02, 15.70, 12.63 and 14.02 μ M, respectively, while the remaining were noncytotoxic (IC₅₀ > 40 μ M).

3. Experimental

3.1. General experimental procedures

Optical rotations were measured on a Jasco P-1020 automatic digital polarimeter. UV spectra were obtained in an HPLC (Agilent 1200, DAD). IR spectra were obtained using a Bruker Tensor 27 FT-IR spectrometer with KBr pellets. NMR spectra were acquired with a Bruker Avance III 600 instrument at room temperature. ESI-MS and EI-MS (including HR-EI-MS) and were measured on Bruker HCT Esquire 3000 and Waters AutoSpec Premier P776 spectrometers. Silica gel (200–300 mesh) and Sephadex LH-20 (Amersham Biosciences, Sweden) were used for column chromatography. Medium pressure liquid chromatography (MPLC) was performed on a Büchi Sepacore System equipping with pump manager C-615, pump modules C-605, and fraction collector C-660 (Büchi Labortechnik AG, Switzerland), and columns packed with Chromatorex C-18 (40–75 μ m, Fuji Silysia Chemical Ltd., Japan). Fractions were monitored by TLC and HPLC (Agilent 1200, Extend-C18 column, 5 μ m, 4.6 × 150 mm).

3.2. Plant material

The stems of *R. verticillata* were purchased from Kunming Chrysanthemum Village medicine market of China, in February 2012 and identified by Mr. Yu Chen of Kunming Institute of Botany, Chinese Academy of Sciences. The voucher specimen (No. BBP0447019RV) was deposited at BioBioPha Co., Ltd.

3.3. Extraction and isolation

The stems of *R. verticillata* (40 kg) were powdered and extracted with EtOH-H₂O (95:5, v/v; 3×70 L, each 5 days) at room temperature, and the solvent was removed under reduced pressure to give crude extract (*ca.* 1.7 kg), then dissolved in 2% HCl (5 L) and filtered. The filtration was basified using 10% ammonia-water to pH 9–10 and then partitioned with EtOAc to give a total alkaloidal extract (*ca.* 280 g), which was fractionated by silica gel CC successively eluted with CHCl₃/MeOH (1:0 \rightarrow 0:1 gradient) to give six fractions A–F.

Fraction B was subjected to MPLC, eluted with MeOH/H₂O (10% \rightarrow 100%), to obtain fractions B1–B4. Fraction B2 was separated by silica gel CC (CHCl₃/MeOH, 100:1 \rightarrow 80:1) to obtain vellosimine (279 mg), akuammidine (10 mg) and reserpine (2 mg). Fraction B3 was purified by MPLC (MeOH/H₂O, 80%) and then Sephadex LH-20 (CHCl₃/MeOH, 1:1) to afford α -yohimbine (54 mg). Fraction B4 was separated by silica gel CC using petroleum ether (PE)/acetone (5:1 \rightarrow 1:1) to afford pelirine (41 mg), β -yohimbine (115 mg) and sitsirikine (13 mg). Fraction C was separated by repeated silica gel CC (CHCl₃/MeOH, 80:1 \rightarrow 10:1) into fractions C1–C3. Peraksine (364 mg) was crystallized from fraction C2, and the mother liquid was passed through a silica gel CC, eluted with CHCl₃/MeOH (80:1 \rightarrow 10:1), to yield tombozine (477 mg) and an inseperable mixture **1/2** (27 mg). Fraction D was separated by silica gel CC (CHCl₃/MeOH, 60:1 \rightarrow 10:1) into fractions D1–D4. Fraction D2

Fig. 3. Key ROESY correlations of 1/2.

Scheme 1. Plausible biosynthetic pathway for 5.

was further purified by preparative TLC (CHCl₃/MeOH, 20:1) to give **5** (37 mg). In the same way, 10-hydroxy-16-epiaffinine (216 mg) and antirhine (90 mg) were obtained from fractions D3 and D4, respectively. Fraction E was subjected to MPLC (MeOH/H₂O, 20% \rightarrow 50%) and then by Sephadex LH-20 (MeOH) to give **3/4** (377 mg), 3-hydroxysarpagine (282 mg), dihydroperaksine (100 mg) and sarpagine (364 mg). Similarly, strictosamide (66 mg), macusine B (359 mg) and spegatrine (704 mg) were obtained from Fraction F.

3.3.1. Rauvovertine A (1)/17-epi-rauvovertine A (2)

White amorphous powder; $[\alpha]_{19}^{19} + 2.5$ (*c* 0.13, MeOH); UV (MeOH) λ_{max} : 222, 277, 288 nm; IR (KBr) ν_{max} 3421, 2971, 2859, 1697, 1628, 1467, 1452, 1396, 1386, 1341, 1295, 1266, 1210, 1175, 1112, 1065, 1041, 1013 cm⁻¹; ¹H and ¹³C NMR data see Tables 1 and 2; ESI-MS (pos.): *m/z* 327 [M + H]⁺; HR-EI-MS: *m/z* 326.1628 (calcd for C₁₉H₂₂N₂O₃, 326.1630).

3.3.2. Rauvovertine B (3)/17-epi-rauvovertine B (4)

White amorphous powder; $[\alpha]_{D}^{19}$ + 32.2 (*c* 0.25, MeOH); UV (MeOH) λ_{max} : 222 (sh), 273, 296 (sh), 307 (sh) nm; IR (KBr) ν_{max} 3406, 2965, 2928, 1697, 1632, 1600, 1456, 1384, 1215, 1146, 1119, 1089, 1054, 1027 cm⁻¹; ¹H and ¹³C NMR data see Tables 1 and 2; ESI-MS (pos.): *m/z* 327 [M + H]⁺; HR-EI-MS: *m/z* 326.1638 (calcd for C₁₉H₂₂N₂O₃, 326.1630).

3.3.3. *Rauvovertine C* (**5**)

White amorphous powder; $[\alpha]_{20}^{26}$ + 9.6 (*c* 0.34, MeOH); UV (MeOH) λ_{max} : 220, 271, 280 (sh), 287 (sh) nm; IR (KBr) ν_{max} 3355, 2940, 2903, 1635, 1453, 1370, 1341, 1181, 1129, 1090, 1075, 1035, 817, 748 cm⁻¹; ¹H and ¹³C NMR data see Tables 1 and 2; EI-MS: *m/z* 321 [M]⁺ (100), 306 (8), 29 (8), 208 (60), 195 (9), 168 (28); HR-EI-MS: *m/z* 321.1849 (calcd for C₂₀H₂₃N₃O, 321.1841).

3.4. Cytotoxicity assay

The following human tumor cell lines were used: HL-60, SMMC-7721, A-549, MCF-7 and SW480. All cells were cultured in RPMI-1640 or DMEM medium (Hyclone, Logan, UT, USA), supplemented with 10% fetal bovine serum (Hyclone) at 37 °C in a humidified atmosphere with 5% CO₂. The cytotoxicity assay was performed according to an MTS [3-(4,5-dimethylthiazol-2-yl)-5-(3-carboxymethoxyphenyl)-2-(4-sulfophenyl)-2*H*-tetrazolium] method with minor modifications, as described previously [26]. The IC₅₀ value of each compound was calculated by the Reed and Muench's method [27].
