China; and ${ }^{3}$ Institute of Tibetan Plateau Research at Kunming, Chinese Academy of Sciences, Kunming, Yunnan 650204, P.R. China

- Premise of the study: Microsatellite markers were developed for Coriaria nepalensis, a traditional Chinese medicinal and ornamental plant, to investigate its genetic diversity and population genetic structure as well as its evolutionary history.
- Methods and Results: Twenty-eight dinucleotide microsatellite loci were identified in C. nepalensis, 20 of which showed polymorphism among five populations. The expected heterozygosities were $0-1$ (mean 0.469 ).
- Conclusions: These markers may be useful for further investigation of the population genetics, systematics, and phylogeography of Coriaria nepalensis.

Key words: Coriaria nepalensis; genetic diversity; microsatellite; polymorphism.

Coriaria is the only genus of Coriariaceae and is widely distributed across four separate areas of the world: East Asia, the Philippines and Pacific islands (New Zealand), Central and South America (from Mexico to Chile), and the Mediterranean. There are three species of Coriaria in China. One of these, Coriaria nepalensis Wall., is a common native shrub species in the central Himalayan region and Southwest China with an elevation of 200-3200 m (Min \& Brach, 2008). It is a pioneer species in secondary forests in hilly regions and is a common ornamental plant. Coriaria nepalensis is a traditional Chinese medicinal plant used to treat numbness, toothaches, traumatic injuries, and acute conjunctivitis (Dictionary of Traditional Chinese Medicine, 1977). Previous research on C. nepalensis has focused on the cytogenetics (diploid, $2 n=40$ ) (Oginuma et al., 1991), chemical constituents (Shen et al., 2004), and molecular phylogeny (Yokoyama et al., 2000). Comparatively little work has been done on its population genetics. Therefore, in this study, 20 polymorphic microsatellite loci of C. nepalensis were developed as potential tools to investigate the genetic structure and genetic diversity of C. nepalensis populations. The classification of Coriaria species is controversial, with unresolved issues about species affinities and the number of constituting species. Therefore, identifying polymorphic microsatellite loci may provide a helpful tool to increase knowledge about the taxonomy and phylogeography of Coriaria and produce useful insights about its biogeography.

## METHODS AND RESULTS

#### Abstract

Genomic DNA was extracted from leaf tissue using a modified cetyltrimethyl ammonium bromide (CTAB) method (Doyle and Doyle, 1987). We constructed an enriched partial genomic library for the repeat motif (AG)n, and then isolated simple sequence repeats (SSRs) using the protocol suggested by Hauswaldt and Glenn (2003). Restriction enzymes RsaI and BSt1 (Fermentas, Burlington, Ontario, Canada) was used to completely digest 500 ng of genomic DNA. The DNA was then ligated to SuperSNX linkers. For enrichment, the ligated products were hybridized with a $5^{\prime}$-biotinylated probe $(\mathrm{AG})_{15}$ in the $100-\mu$ l hybridization solution ( $12 \times \mathrm{SSC}$ and $0.2 \% \mathrm{SDS}$ ) at $95^{\circ} \mathrm{C}$ for 5 min , quickly ramped to $48^{\circ} \mathrm{C}$, and maintained this temperature for 2 h . Hybridized DNA was then mixed with Streptavidin-coated magnetic beads (Promega, Madison, Wiscon$\sin$, USA). Captured DNA was recovered as the template to amplify using the SuperSNX-Forward primer ( $5^{\prime}$-GTTTAAGGCCTAGCTAGCAGAATC-3'). PCR products were purified with a PCR products purification kit (TIANGEN, Beijing, China), and then these fragments containing microsatellite loci were cloned using pMD18-T vector (Takara, Dalian, Liaoning, China) according to the manufacturer's instructions and propagated in an E. coli DH5 $\alpha$ strain. Positive clones were amplified using (AG) 10 and M13 primers. PCR products ranging from 200 to 800 bp were selected for sequencing. Of the 81 clones sequenced, 80 contained potential microsatellite motifs. Of these, 42 clones with unique microsatellites were selected for designing primers using Primer 5.0 (Clarke \& Gorley, 2001).

Polymorphism was evaluated in 45 individuals of C. nepalensis from five populations in the Yunnan Province of Southwest China. These included 11 individuals from the ZXS population, nine from BG, 10 from LJ, eight from ML, and seven from SM (Table 1). Voucher specimens were deposited in the herbarium of the Kunming Institute of Botany, Chinese Academy of Sciences. PCR was performed in $20-\mu \mathrm{L}$ volume using a PTC0200 thermal cycler (BIO-RAD, Foster City, California, USA). Each reaction was performed using 20 ng of genomic DNA, $1 \mu \mathrm{M}$ of each $\mathrm{dNTP}, 1 \mu \mathrm{M}$ of each primer, $1 \times$ Taq buffer $(100 \mathrm{mM}$ Tris- $\mathrm{HCl}, \mathrm{pH} 8.8,2.0 \mathrm{mM} \mathrm{MgCl}, 200 \mathrm{mM}\left(\mathrm{NH}_{4}\right)_{2} \mathrm{SO}_{4}, 0.1 \%$ Tween 20) and 1 U of Taq polymerase (Takara, Dalian, Liaoning, China). The PCR program was: initial denaturing step at $94^{\circ} \mathrm{C}$ for $3 \mathrm{~min}, 30$ cycles of $94^{\circ} \mathrm{C}$ for 30 s each, primer-specific annealing temperature of $50-58^{\circ} \mathrm{C}$ for $30 \mathrm{~s}, 72^{\circ} \mathrm{C}$ for 60 s , and a final extension step at $72^{\circ} \mathrm{C}$ for 8 min . The PCR products were electrophoresed in denaturing $6 \%$ polyacrylamide gels using a $25-\mathrm{bp}$ DNA ladder molecular size standard (Fermentas, Burlington, Ontario, Canada) to estimate allele sizes by silver staining.

Of the 42 new primers, 28 primer pairs successfully amplified products with expected size. Twenty of them displayed polymorphism across populations,

Table 1. Sample information of Coriaria nepalensis

| Population | Location | Position | Altitude (m) | Sample size | Voucher (Herbarium) |
| :---: | :---: | :---: | :---: | :---: | :---: |

A, number of alleles; $\mathrm{H}_{\mathrm{E}}$, expected heterozygosity; statistically significant deviation from Hardy-Weinberg equilibrium is indicated by * $(P<0.01)$.
whereas eight primer pairs displayed monomorphism (Table 2). The number of alleles per locus, expected heterozygosity $\left(H_{E}\right)$, and deviation form HardyWeinberg equilibrium (HWE) were assessed using GENEPOP version 3.4 (Raymond \& Rousset, 1995). The number of alleles per locus ranged from 2 to 5 with an average of 3.2 (Table 3). The expected heterozygosities $\left(H_{E}\right)$ ranged from 0 to 1 , with an average of 0.469 (Table 3). Among the 20 polymorphic microsatellite markers, six loci showed significant deviation from Hardy-Weinberg equilibrium $(P<0.01)$ (Table 3). These were due to deficiency of heterozygotes or the limited sample size. Tests for linkage disequilibrium were run in FSTAT version 2.9.3.2 (Goudet, 1995). In additional, no loci showed significant linkage disequilibrium between locus pairs after the Bonferroni correction.

## CONCLUSIONS

Twenty of the 42 microsatellite makers are polymorphic. These newly developed nuclear microsatellite markers will be a useful tool for studying the population genetics of Coriaria nepalensis. In additional, the set of novel makers are also helpful for further studies of the systematics, phylogeography and evolutionary history of Coriaria.
