#### Abstract

Incarvillea mairei (H. Léveillé) Grierson (Bignoniaceae) is an endemic species to the HimalayaHengduan Mountains region. Here, we developed 13 microsatellite markers from I. mairei using a modified biotin-streptavidin capture method. Number of alleles per locus (NA) ranged from 3 to 7 with an average of 4.615. The observed $\left(H_{\mathrm{O}}\right)$ and expected $\left(H_{\mathrm{E}}\right)$ heterozygosities were from 0.050 to 0.800 and from 0.249 to 0.815 , respectively. Additionally, among the 13 identified microsatellite markers, 12 of them were successfully amplified in other three congeneric species, and most of them showed polymorphic. Obtained evidences suggest that these markers provide a useful tool for further study of the population genetic structure and the breeding system in this species or/and infra-generic species.

## Introduction

Incarvillea Juss is a notable genus with herbaceous and temperate distributed species in contrast with other woody and tropical distributed members in family Bignoniaceae. The diversification of some herbaceous species appears to have involved rapid migration, geographic isolation and reproductive isolation, and is considered to be related to the uplift of the Himalaya Mountains (Wu et al. 2003; Chen et al. 2005). Incarvillea mairei (H. Léveillé) Grierson, a perennial herb, is endemic to the Himalaya-Hengduan Mountains region and particularly occurs in rocky grass slopes and meadows at altitudes ranging from 2,500 to $4,500 \mathrm{~m}$. It is very interesting that this early-flowering species bears specific floral structures, which are characterized by a large sensitive stigma composed of two lobes and the anther-appendage. Our primary study showed that a set of reproductive strategies of this species were able to ensure reproductive success in harsh alpine environment. In order to further investigate its genetic structure and the breeding system, here we developed 13 microsatellite markers from I. mairei, and tested their utility for other three congeneric species (i.e. I. arguta, I. lutea and I. younghusbandii).

Genomic DNA samples of I. mairei were extracted from silica-gel-dried leaves using a CTAB methodology (Doyle and Doyle 1987). A microsatellite enriched library was then conducted using a modified biotin-streptavidin capture method (Chen et al. 2008). In brief, total genomic DNA (approximate $500-1,000 \mathrm{ng}$ ) was completely digested with 2.5 U of MseI restriction enzyme (NEB), and then was ligated to a specific MseI AFLP adaptor using T4 DNA ligase (New England Biolabs). The digested-ligated fragments were diluted in a ratio of $1-10$, and $5 \mu \mathrm{l}$ of them were used for amplification reaction with adaptor-specific

Table 1 Characteristics of 13 microsatellite loci developed for Incarvillea mairei

| Locus | Primer sequence ( $5^{\prime}-3^{\prime}$ ) | Repeat motif | Size range (bp) | $T_{\mathrm{a}}\left({ }^{\circ} \mathrm{C}\right)$ | NA | $H_{O}$ | $H_{E}$ |

NA, number of observed alleles; $T_{\mathrm{a}}, \mathrm{PCR}$ annealing temperature; $H_{\mathrm{O}}$, observed heterozygosity; $H_{\mathrm{E}}$, excepted heterozygosity; Statistically significant deviation from Hardy-Weinberg expectation is indicated by $*(P<0.01)$
primers ( $5^{\prime}$-GATGAGTCCTGA GTA AN-3'). The amplified DNA fragments, with a size range of $200-800 \mathrm{bp}$, were hybridized to a 5-biotinylated [(AG) ${ }_{15}$, (AAG) ${ }_{10}$ or (AC) ${ }_{15}$ ] probe, then selectively separated and captured by streptavidin-coated magnetic beads (Promega) (Zane et al. 2002). The recovered DNA fragments were re-amplified with MseI-N primers. The purified PCR products using EZNA Gel Extraction Kit (Omega Bio-Tek), were then ligated into PGEM-T vector (Promega), and transformed into $\mathrm{DH} 5 \alpha$ competent cells (Tiangen). The positive clones were tested using vector primers SP6/T7 and specific primer (AC) ${ }_{10} /(\mathrm{AG})_{10} /(\mathrm{AAG})_{7}$, respectively. In total, 240 positive clones were sequenced with an ABI PRISM 3730XL DNA sequencer, and 130 clones contained microsatellites. Finally, a total of 80 primer pairs were predicted suitable for primer designing using Primer 5.0 (Clarke and Gorley 2001).

Polymorphisms of all 80 microsatellite loci were assessed in 40 individuals of I. mairei from six populations in the Himalaya-Hengduan Mountains region. The PCR
reactions were performed in $15 \mu \mathrm{l}$ of reaction volume containing $30-50 \mathrm{ng}$ genomic DNA, $0.6 \mu \mathrm{M}$ of each primer, $7.5 \mu \mathrm{l} 2 \times$ Taq PCR MasterMix (Tiangen; 0.1 U Taq Polymerase $/ \mu \mathrm{l}, 0.5 \mathrm{mM}$ dNTP each, 20 mM Tris-HCl ( pH 8.3 ), $100 \mathrm{mM} \mathrm{KCl}, 3 \mathrm{mM} \mathrm{MgCl} 2$ ). PCR amplifications were conducted under the following conditions: $94^{\circ} \mathrm{C}$ for 3 min followed by $30-36$ cycles at $94^{\circ} \mathrm{C}$ for 30 s , at the annealing temperature for each specific primer (optimized for each locus, Table 1) for $30 \mathrm{~s}, 72^{\circ} \mathrm{C}$ for 1 min , and a final extension step at $72^{\circ} \mathrm{C}$ for 8 min . PCR products were separated on $8 \%$ polyacrylamide denaturing gel using a 20-bp ladder molecular size standard by silver staining.

In all, PCR products with 13 primer pairs displayed polymorphisms among different populations. Standard genetic diversity parameters, departure from Hardy-Weinberg equilibrium (HWE) and linkage disequilibrium between pairs of loci were estimated in GENEPOP version 4.0 (Raymond and Rousset 1995). The number of alleles per locus (NA) was 3-7 with an average of 4.615 , values for observed $\left(H_{\mathrm{O}}\right)$ and expected $\left(H_{\mathrm{E}}\right)$ heterozygosities

Table 2 Cross-species amplification of 13 polymorphic microsatellite loci islolated from Incarvillea mairei in I. arguta, I. lutea and I. younghusbandii

| Locus | I. arguta <br> $(n=8)$ | I. lutea <br> $(n=8)$ | I. younghusbandii <br> $(n=8)$ |
| :--- | :--- | :--- | :--- |
| IM2 | W | M | $\mathrm{P}(2)$ |
| IM6 | NA | $\mathrm{P}(3)$ | $\mathrm{P}(4)$ |
| IM7 | W | $\mathrm{P}(3)$ | $\mathrm{P}(5)$ |
| IM26 | W | $\mathrm{P}(3)$ | M |
| IM28 | W | $\mathrm{P}(2)$ | $\mathrm{P}(4)$ |
| IM30 | $\mathrm{P}(3)$ | $\mathrm{P}(2)$ | $\mathrm{P}(3)$ |
| IM32 | W | $\mathrm{P}(3)$ | M |
| IM33 | W | M | W |
| IM48 | W | $\mathrm{P}(3)$ | $\mathrm{P}(3)$ |
| IM73 | M | $\mathrm{P}(3)$ | $\mathrm{P}(4)$ |
| IM75 | $\mathrm{P}(3)$ | $\mathrm{P}(2)$ | $\mathrm{P}(3)$ |
| IM76 | $\mathrm{P}(2)$ | $\mathrm{P}(3)$ | $\mathrm{P}(3)$ |
| IM78 | $\mathrm{P}(3)$ | $\mathrm{P}(2)$ | $\mathrm{P}(4)$ |

$N A$ no amplification, $W$ weak amplifications, $M$ monomorphic amplification, $P$ polymorphic amplification
ranged from 0.050 to 0.800 and from 0.249 to 0.815 , with averages of 0.462 and 0.608 , respectively (Table 1). For all 13 microsatellite loci, except IM6, IM7, IM26, IM28, IM76 and IM78, the genotypic frequencies showed significant deviation from HWE $(P<0.01)$ indicating the possibility of null alleles, non-random mating, or the Wahlund effect. Significant LD was detected in four locus pairs: (IM6, IM7), (IM26, IM6) (IM73, IM7) and (IM73, IM6).

Cross-species amplification in other three species (I. arguta, I. lutea and I. younghusbandii) was tested using eight individuals each. Twelve of them were successfully amplified in all three congeneric species, whereas the primer IM6 failed to amplify in I. arguta, and most of them revealed polymorphism in various species (Table 2).

Eleven microsatellite loci ( $84.62 \%$ ) showed polymorphisms in I. lutea, ten loci (76.92\%) in I. younghusbandii and four loci $(30.77 \%)$ in I. arguta, respectively. The results indicated that there was a high potential for transferring microsatellite markers in the genus Incarvillea. Therefore, the 13 novel polymorphic microsatellite loci developed here will be useful for understanding the population genetic structure and further investigating the breeding system and gene flow patterns of I. mairei and its related species.

Acknowledgments This study was supported by National Basic Research Program of China (973 Program, No. 2007CB411603). We would like to thank Dr. Zhen-Hua Guo for revising this manuscript. And we are grateful to Dr. Yuan Huang, Mr. Xing-Feng Zhao and Miss Yang Yang for their kindly assistance on the procedure of experiments.
