ABSTRACT

Two novel sesterterpenoids, leucosceptroids C (1) and D (2), possessing unusual antipodal cyclopentenones while maintaining the stereochemistry and functionality of the tricyclic cores, were discovered from the leaves of Leucosceptrum canum (Labiatae). Their structures including absolute stereochemistries were determined by comprehensive NMR, MS, and single-crystal X-ray diffraction analyses. The potent antifeedant activity of 1 against the generalist plant-feeding insect Helicoverpa armigera (EC50 = 0.017 μmol/cm2) suggested them to be new defensive sesterterpenoids of L. canum.

Terpenoids are the largest group of natural products with highly diversified chemical structures and a variety of roles including especially a defensive function in the natural world.1 Most terpenoids are cyclized to form various skeletons containing one or more rings. Cyclizations of natural terpenoids are catalyzed by terpenoid cyclases and are the most complex chemical reactions with remarkable stereochemical precision in Nature.2

Among plants of southwest China, Leucosceptrum canum Smith, a woody plant belonging to the family Labiatae (= Lamiaeceae), is perhaps the largest (up to 10 m high3) and so far the only colored nectar plant4 of all Labiatae species and is found in the Himalayas to the southwest of China.4 This plant is rarely attacked by herbivores and only occasionally by pathogens. We have been interested in the relationship between the secondary metabolites of L. canum and its above special traits and have found that glandular trichomes of L. canum could harbor unique defensive sesterterpenoids, leucosceptroids A and B (Figure 1).5 Our further investigation on the defensive sesterterpenoids in the leaves led to the discovery of two additional intriguing sesterterpenoids, leucosceptroids C (1) and D (2) (Figure 1), possessing novel C25 carbon frameworks containing unusual antipodal cyclopentenones while maintaining the stereochemistry of the other rings and substituents. In this communication, we report their isolation, structure determination including absolute stereochemistries,

and antifeedant activity against the generalist plant-feeding insect Helicoverpa armigera.

Compound 1 was obtained as colorless blocks, having a molecular formula of C_{25}H_{36}O_{6}, as determined by its negative FAB-MS and high resolution ESI-MS. The IR spectrum indicated the presence of hydroxyl groups (3513 and 3413 cm\(^{-1}\)) and ketone groups (1705 cm\(^{-1}\)). In the \(^1H\) NMR spectrum (Table 1 and Figure S5), two secondary methyls at \(\delta_1^H\) 0.79 (d, \(J = 7.4\) Hz) and 0.94 (d, \(J = 6.8\) Hz) and four tertiary methyls at \(\delta_1^H\) 1.27 (s), 1.70 (br s), and 1.72 (6H, s) were clearly shown. Two olefinic protons at \(\delta_1^H\) 5.57 (d, \(J = 8.8\) Hz) and 7.20 (br s) indicated the presence of two trisubstituted double bonds. Four singlets at \(\delta_1^H\) 2.76, 4.46, 4.58, and 4.63 and two doublets at \(\delta_1^H\) 4.68 (\(J = 2.8\) Hz) and 4.76 (\(J = 8.8\) Hz) were ascribable to either methine or free hydroxyl groups. Other signals occurred in a relatively high-field region (between 1.38 and 2.43 ppm) and mostly overlapped, resonating from either methine or methylene signals. The \(^13C\) NMR and DEPT spectra (Table 1 and Figure S6) exhibited 25 carbon resonances, corresponding to two keto carbons, seven methines including two oxymethines, three hydroxy groups, two double bonds, three oxygenated quaternary groups, and six methyls. These data were consistent with the signals observed in \(^1H\) NMR spectrum.

The resemblance of NMR spectral data of 1 with those of leucosceptroid A indicated that their D rings in the southern hemisphere were distinct from each other. An \(\alpha,\beta\)-unsaturated keto moiety, substituted by a methyl group at the \(\alpha\)-position, could be easily recognized in 1. The coupling relationships of H-16/H-20/H-19 was established by \(^1H\)–\(^1H\) correlations (Figure S9), which allowed direct linkages between C-16 and C-20 and between C-20 and C-19 in 1. The \(^1H\)–\(^13C\) correlations (Figures S1 and S8) from H-16 to C-17 indicated a connection between C-16 and C-17. Thus the furan ring in leucosceptroid A was replaced by a cyclopentenone in 1. A free hydroxyl group at \(\delta_1^H\) 4.68 (d, \(J = 2.8\) Hz) was assignable to C-20, based on its \(^1H\)–\(^1H\) correlation with H-20 and HMBC correlations with C-20, C-19, and C-16.

correlations for rings A, B, and C (Table S1 and Figure S10). However, it was not possible to use ROESY experiments to identify the stereochemistry of the two chiral centers (C-16 and C-20) in ring D. To solve this problem, an X-ray diffraction of 1 was necessary. A single crystal of 1 was successfully obtained from a mixture of petroleum ether/acetone (1:2), and X-ray crystallographic analysis was carried out with molybdenum radiation (CCDC 810481), which confirmed the deduced structure and established the relative stereochemistry of 1 as shown in Figure S2.

The FAB-MS (negative ion mode) and HR-ESI-MS\(^7\) of 2 indicated a molecular formula of \(C_{25}H_{36}O_5\), which was only one oxygen atom less than that of 1. The close resemblance between the NMR spectra of 2 (Table I and Figures S11–16) and those of 1 indicated that 2 was another sesterterpenoid structurally similar to 1. The major difference was the replacement of an oxyquaternary carbon in 1 by a methine group in 2 (\(\delta_c 65.1\)). The long-range \(\text{H} - ^{13}\text{C}\) correlations (Figure S3) from H-7, H-10, and Me-23 to this methine carbon, and from the corresponding mething proton (\(\delta_H 1.83\)) to C-7, C-10 and C-12, indicated this methine carbon to be C-11. Accordingly, compound 2 was identified as an 11-dehydroxy derivative of 1.

In the ROESY spectrum (Table S1 and Figure S16) of 2, correlations between H-11 and H-8a, H-9e, and Me-23 suggested H-11 to be \(\alpha\)-oriented, as has been found in leucosceptroid B (Figure 1), another defensive sesterterpenoid in glandular trichomes of \(L.\ canum\). Other ROEs of 2 implied that the relative stereochemistry of the remaining chiral centers in the core structure of 2 were identical to those in 1 and leucosceptroid B. Although the stereochemistry of ring D of 2 was not possible to determine with ROESY experiments, it was originally thought to be identical to that of 1, since the chemical shifts of H/C-16 and H/C-20 of the two compounds were so close to each other, and the cyclizations of terpenoids are usually highly stereospecific. However, to our surprise, X-ray crystallographic analysis on a single crystal of 2 (obtained from a mixture of acetone/H\(_2\)O, 10:0.1) with molybdenum radiation (CCDC 810483) (Figure S4), while confirming the deduced structure and the relative stereochemistry of the core structure (A, B, and C rings) of 2, disclosed that the stereochemistry of ring D of 2 was opposite to that of 1.

To further confirm the above observation, X-ray crystallographic analyses of both 1 and 2 using anomalous dispersion with copper radiation were performed (CCDCs 810480 and 810482) (Figures 2 and 3), which determined the absolute stereochemistry of 1 to be \(4R,5R,6S,7S,10S,11R,13R,14S,16S,20R\) and the absolute stereochemistry of 2 to be \(4R,5R,6S,7S,10S,11R,13R,14S,16R,20S\). Thus, the two sesterterpenoids were concluded to possess unusual antipodal cyclopentenones (D ring) while maintaining other rings (A, B, and C) still highly stereospecific. Consequently, compounds 1 and 2 were identified as shown in Figure 1 and were named leucosceptroids C and D respectively.

![Figure 2. X-ray crystallographic structure of 1 showing the absolute stereochemistry.](image)

It has been well-known that cyclizations of natural terpenoids are catalyzed by terpenoid cyclases, mostly with incredible stereochemical precision.\(^6\) Despite this, antipodal cyclizations catalyzed by a few unusual terpene cyclases were also reported.\(^8\) The antipodal cyclopentenones in leucosceptroids C and D (1 and 2) were presumably formed by intramolecular aldol condensation of an intermediate [A] catalyzed by similar unusual cyclases as proposed in Scheme 1, which might also be completed in the glandular trichomes of \(L.\ canum\) and then either stored within the gland cavity or secreted onto the leaves. Interestingly, we have noticed that a series of natural sesquiterpenes named litseaverticillols,\(^5\) which were isolated from \(L.\ verticillata\) and possessed identical cyclopentenones with those in leucosceptroids C and D (1 and 2), occurred exclusively as racemates, indicating that antipodal cyclopentenones also exist in litseaverticillols because the chiral centers of these compounds present only in their cyclopentenone rings. Therefore, it is very likely that natural antipodal cyclizations of cyclopentenones in terpenoids, albeit unusual, may be a common property of the

\(^{(7)}\) Leucosceptroid D (2): colorless blocks; \(\alpha_{D}^{22} = +3.7 (c = 0.3, \text{MeOH})\); UV (MeOH) \(\lambda_{max} (\log e): 205 (3.25) \text{ nm;} \) IR (KBr) \(\nu_{max}: 3427, 2935, 2871, 1712, 1632, 1453, 1374, 1329, 1035, 925 \text{ cm}^{-1};\) negative FAB-MS \(m/z (\%) = 415(17) [\text{M} - \text{H}], 397 (90), 339 (20), 255 (48);\) HR-ESI-MS: \(m/z = 415.2486 [\text{M} - \text{H}]^{-} (m/z_{calcd}[C_{25}H_{36}O_5]) = 415.2484\).

responsible enzyme type in plants. Consequently, the stereochemistry of cyclopentenones in another sesterterpenoid from *Salvia hypoleuca*, salvileucolidone,\(^\text{(10)}\) is still to be finalized. The isomer of salvileucolidone with an antipodal cyclopentenone, although not reported so far, should also exist in *S. hypoleuca*. Likewise, the diastereomer of leucosesterterpenone\(^\text{(11)}\) with an antipodal cyclopentenone should also be a metabolite of Nepalese *L. canum*.

The antifeedant activity of leucoseptroid C (1) against a generalist insect, cotton bollworm (*Helicoverpa armigera*), was assayed as described previously.\(^\text{5}^\) The compound showed potent antifeedant activity, with an EC\(_{50}\) of 0.017 μmol/cm\(^2\). It was slightly more active than leucoseptroid B (EC\(_{50}\) = 0.021 μmol/cm\(^2\))\(^\text{5}^\) and nearly three times the potency of leucoseptroid A (EC\(_{50}\) = 0.049 μmol/cm\(^2\))\(^\text{5}^\) in deterring plant-feeding insect *H. armigera*, suggesting a similar defensive role of 1 against herbivore enemies. Although leucoseptroid D (2) was not assayed for its antifeedant activity due to an insufficient sample, it is probably also active against insect herbivores since a change of the side chain in the southern hemisphere of this new class of compounds does not significantly affect the antifeedant activity.

In conclusion, we have discovered two additional novel defensive sesterterpenoids with unusual antipodal cyclopentenones from the leaves of *L. canum* and determined their absolute stereochemistries with a single-crystal X-ray diffraction study using anomalous dispersion with copper radiation and found their potential defensive function, which will help to disclose the relationship between the unique secondary metabolites of *L. canum* and its special traits “large woody” and “colored nectar”.
