Received 20 September 2001; accepted 10 October 2001

#### Abstract

The effect of $O, S$ and $N$ atoms in aromatic ring substituents at C-1 position of tetrahydro- $\beta$-carboline ligands on the enantioselectivity of diethylzinc additions to benzaldehyde was studied when esters or tertiary alcohol functions were present at C-3. A mechanism is proposed to explain why the ester ligands $\mathbf{2 c}$ and $\mathbf{2 d}$, in which the pyridyl $N$ atom is at $\mathrm{C}^{\prime}-2$ in $\mathbf{2 c}$ and at $\mathrm{C}^{\prime}-3$ in 2d, catalyzed the addition of diethylzinc to benzaldehyde to form the $(R)$ - and ( $S$ )-enantiomers of 1-phenyl-1-propanol, respectively. An explanation was also proposed for the moderate enantioselectivity induced by tert-alcohol $3 \mathbf{c}$ versus the very small enantioselectivity induced by 3d, containing a 3-pyridyl function at $\mathrm{C}-1$, during diethylzinc additions. A $-\mathrm{CH}_{2}-t-\mathrm{Bu}$ substituent at C-1 leads to very high enantioselectivities. © 2001 Elsevier Science Ltd. All rights reserved.

## 1. Introduction

Asymmetric $\mathrm{C}-\mathrm{C}$ single bond formation is fundamental to the construction of designed chiral target molecules. Various chiral molecules have been synthesized using chiral ligands. Many chiral catalysts and organometallic reagents have been employed in enantioselective additions and other reactions. ${ }^{1}$ We recently reported that $1,2,3,4$-tetrahydro- $\beta$-carboline amino acid esters, derived from a natural alkaloid, act as chiral ligands, exhibiting moderate enantioselectivities and yields during the addition of diethylzinc to benzaldehyde. ${ }^{2 b}$ Herein, we describe the total synthesis of these amino acid ester and corresponding tertiary alcohol ligands. Also, the effect of $O, S$ and $N$ heteroatoms in aromatic ring substituents located at $\mathrm{C}-1$ on the enantioselectivity of diethylzinc addition reaction was examined. A mechanism is proposed to explain why the ligand $\mathbf{2 c}$, in which $N$ atom is at $\mathrm{C}^{\prime}-2$ in the pyridyl ring, gives ( $R$ )-1-phenyl-propanol while ligand $\mathbf{2 d}$, where the pyridyl $N$ atom is at $\mathrm{C}^{\prime}-3$, produced the $(S)$-enantiomer

[^0]during addition of diethylzinc to benzaldehyde. The difference in enantioselectivity induced by 2-pyridylcontaining ligand 3c (moderate e.e.) versus 3-pyridyl analog, 3d (poor e.e.) is discussed and an explanation proposed.

## 2. Results and discussion

The non-racemic chiral amino acid ester ligands $\mathbf{2 a}-\mathbf{2 f}$ were synthesized from the natural alkaloid abrine. Abrine is an unusual amino acid, which is easily available from the seed of Abrus precatorius collected in Yunnan Province, China. After esterification of abrine to methyl ester, 1, the Pictet-Spengler condensation reaction ${ }^{3}$ (Scheme 1) produced the corresponding chiral amino acid esters of the 1,2,3,4-tetrahydro- $\beta$-carboline series $\mathbf{2 a}-\mathbf{f}$. These were used as the chiral ligands in the diethylzinc addition reaction. The enantioselectivities were determined at ambient temperature in toluene using $10 \mathrm{~mol} \%$ of the ligand (Eq. (1) and Table 1).

The corresponding tertiary alcohol ligands 3a-f were synthesized by the addition of ethylmagnesium chloride in THF to 2a-f, respectively. Enantioselectivities induced by ligands $\mathbf{3 a - f}$ in diethylzinc additions to benzaldehyde are summarized in Table 2.

${ }^{\text {a }} 10 \%$ mol catalyst used, the mole ratio of $\mathrm{Et}_{2} \mathrm{Zn} / \mathrm{PhCHO}$ is 2.0, the reactions were carried out in toluene at room temperature.
${ }^{\mathrm{b}}$ Based on the isolated compound.
${ }^{c}$ Determined using a Chiracell OD column and eluting with isopropanol and $n$-hexane (5:95) at the flow rate $1 \mathrm{ml} / \mathrm{min}$.
${ }^{\mathrm{d}}$ The specific rotation value and rotation direction of 1-phenyl-1-propanol were used as the standard for the determination of the configuration of 1-phenyl-1-propanol, see Ref. 4 for the details.

The $O$ and $S$ atoms in the furan and thiophene rings of $\mathbf{2 a}$ and $\mathbf{2 b}$ have a much smaller effect on enhancing the enantioselectivity than the pyridyl nitrogen in $2 \mathbf{c}$ and 2d. Both 2 c and 2 d give the $R$ configuration of 1-phenyl-1-propanol versus the $S$ configuration which was favored using 2a and $\mathbf{2 b}$ (Table 1, entries 1, 2 and $3)$.

When the pyridyl nitrogen is meta to the bond connecting this ring to the $\beta$-carboline ring system 2d, the opposite ( $S$ )-enantiomer is formed and the e.e. is very
small (Table 1, entries 3 and 4). When the pyridyl ring at $\mathrm{C}-1$ is replaced by a phenyl ring 2 e , the $e . e$. is still low and the $(S)$-enantiomer of 1-phenyl-1-propanol is formed. A mechanism which explains the configuration changes is proposed using transition state (TS) structures 6-8. In general, the favored TS is described by 6 when there is no $N$ atom at $\mathrm{C}^{\prime}-2$. However, when there is a $N$ atom at $\mathrm{C}^{\prime}-2$, the ability of nitrogen to chelate with Zn changes the structure of the TS to 7 . We propose that TS 7 has the lower energy. Thus, using ligand 2 c leads to the $R$ configuration of 1-phenyl-1propanol as the major product.

${ }^{\text {a }} 5 \%$ mol catalyst used in toluene at room temperature at a $\mathrm{Et}_{2} \mathrm{Zn} / \mathrm{PhCHO}$ mole ratio of 2.0.
${ }^{\mathrm{b}}$ Based on the isolated compound.
${ }^{\text {c }}$ Determined using a Chiracell OD column eluting with isopropanol and $n$-hexane (5:95) at the flow rate of $1.0 \mathrm{ml} / \mathrm{min}$ (detected by UV at 254 nm ).
${ }^{\mathrm{d}}$ The specific rotation value and rotation direction of 1-phenyl-1-propanol were used as the standard for the determination of the configuration of 1-phenyl-1-propanol, see Ref. 4 for the details.
${ }^{\mathrm{e}}$ See Ref. 2e for details.

When the pyridyl $N$ atom is located at $\mathrm{C}^{\prime}-3$ position 2d, this nitrogen ( $\mathrm{N}^{2}$ ) cannot chelate with $\mathrm{Zn}^{2}$. Therefore, the TS structures $\mathbf{8 a}$ and $\mathbf{8 b}$ are postulated to be favored instead of structures like 6 or 7 . Two competitive pathways could operate using 2 d as represented by TS 8a and TS 8b. The presence of $\mathrm{Et}^{2 \mathrm{~b}}$ forces the Ph group in benzaldehyde to be up and this geometry must be a pro- $S$ center. The smaller ring system in TS 8a ( $5 / 4 / 4$ ) could be kinetically favorable versus the larger ring system in $\mathbf{8 b}$. A small contribution from the pathway through $\mathbf{8 b}$ would lead to the predominance of the $S$ configuration.

The amino alcohol ligands, 3a-f, derived from esters 2a-f can catalyze the diethylzinc addition to form ( $R$ )-1-phenyl-1-propanol. Ligand 3d induced much lower enantioselectivity than $\mathbf{3 c}$. The nitrogen at $\mathrm{C}^{\prime}-3$ exerts a different effect than the $\mathrm{C}^{\prime}-2$ nitrogen. Possible TS structures 9 and 10 are proposed. The pyridyl nitrogen $\left(\mathrm{N}^{2}\right)$ in 9 can easily chelate with Zn (forming a 5 -membered ring) and giving a trichelated TS structure. How-
ever, the pyridyl nitrogen of $\mathbf{3 d}$ cannot chelate with $\mathrm{Zn}^{1}$ in TS $\mathbf{1 0}$ because it would require significant ring strain. In this case, the pyridyl nitrogen $\left(\mathrm{N}^{2}\right)$ chelates the other $\mathrm{ZnEt}_{2}$, instead, and at the same time, $\mathrm{Zn}^{1}$ can accept a lone pair coordination from the PHCHO oxygen. When the $\mathrm{Et}^{2 \mathrm{~b}}$ group is absent, benzaldehyde's phenyl ring in 10a should be down. This forms a pro- $R$ center. The small ring system (5/4/4) TS, 10a, is more stable which would lead to a major product that has the $R$ configuration. However, competition results in the low enantioselectivity. These experimental results are summarized in Table 2.

Table 3 lists the enantioselectivity of chiral ligand $\mathbf{3 f}$ using different aldehydes as the substrates (Eq. (2)). Ligand $3 f$ contains the bulky 2,2-dimethylpropyl substituent at $\mathrm{C}-1$ which exhibits the ability to produce high e.e. values in diethylzinc additions to aldehydes. Perhaps steric effects, which promote high e.e. values with seven aldehydes (Table 3), can also account for the unexpected observation that $\mathbf{3 f}$ can't induce enantiose-

lectivity during the addition of diethylzinc to 2 -naphthyl aldehyde and cinnamyl aldehyde. Many common chiral ligands give lower enantioselectivities in additions to aliphatic aldehydes than to aromatic aldehydes. However, 3f produced excellent enantioselectivities with the aliphatic aldehydes tested.

## 3. Experimental

${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra were recorded on AM-400 NMR and Bruker-300 NMR instruments. IR spectra were taken on a spectrometer. Melting points were recorded using a microscope melting point apparatus and were uncorrected. Optical rotations were recorded on a Perkin Elmer 241 polarimeter at $22^{\circ} \mathrm{C}$. High resolution mass spectra (HRMS) were obtained using a VG-Autospec mass spectrometer and elemental analyses were performed on a Model-1106 instrument. All reactions were carried out under nitrogen protection and followed with TLC using UV active plates (F-254) or by spraying with $10 \%$ ethanol phosphomolybdic acid and heating. $\mathrm{Et}_{2} \mathrm{Zn}$ ( 1.0 M in toluene) and other reagents were obtained commercially and used as received.

### 3.1. General procedures

3.1.1. Pictet-Spengler condensations. The aldehyde ( 1.05 equiv.) was injected into a solution of abrine methyl ester ( 1.0 equiv.) and TFA ( 0.25 equiv.) in dry dichloromethane in the presence of $4 \AA$ molecule sieves and stirred overnight. After filtering and washing the flask with ethyl acetate, the combined organic solution was evaporated under reduced pressure. The residue was purified by flash column chromatography (silica gel) using ethyl acetate and hexane ( $10: 90$ to $30: 70$ ) as eluant to give the $1,2,3,4$-tetrahydro- $\beta$-carboline methyl esters.
3.1.2. Addition of ethyl Grignard to $\mathbf{1 , 2 , 3 , 4 - t e t r a h y d r o - ~} \beta$ carbolines. The solution of $1,2,3,4$-tetrahydro- $\beta$-carboline ( 1.0 mmol ) in dry THF was cooled with an external ice-bath. Then the ethyl magnesium chloride Grignard reagent (4-5 equiv.) in THF was added by syringe under nitrogen protection. Then the solution was allowed to warm to room temperature. After the reaction was completed (checked with TLC), it was quenched with water while cooling with an ice-bath. The solution was extracted with ethyl acetate and the combined organic layer was dried over anhydrous

${ }^{\text {a }} 5 \%$ mol catalyst used in toluene at room temperature at a $\mathrm{Et}_{2} \mathrm{Zn}$ /aldehyde mole ratio of 2.0
${ }^{\mathrm{b}}$ Based on the isolated compound.
${ }^{\text {c }}$ Determined using Chiracell OD column eluting with isopropanol and $n$-hexane (5:95) at the flow rate of $1.0 \mathrm{ml} / \mathrm{min}$ (detected by UV at 254 nm ) except entry one.
${ }^{\mathrm{d}}$ The specific rotation values and rotation directions of the known compounds were used as the standard for the determination of the configuration for all addition alcohols, see Ref. 5 for the details.
${ }^{\mathrm{e}}$ The cyclohexanol was converted into benzyl ester and determined with double Chiralcell AD column eluting with isopropanol and $n$-hexane (3:97) at the flow rate of $1.0 \mathrm{ml} / \mathrm{min}$ (detected by UV at 254 nm ).
$\mathrm{MgSO}_{4}$. The organic solvents were evaporated under reduced pressure. The residue was purified by flash column chromatography (silica gel) using ethyl acetate and hexane ( $10: 90$ to $30: 70$ ) to give the $1,2,3,4$-tetra-hydro- $\beta$-carboline alcohol.
3.1.3. Catalytic enantioselective additions of diethylzinc to aldehydes. $\mathrm{A}_{2} \mathrm{Zn}$ solution $(4.0 \mathrm{ml}, 1 \mathrm{M}$ in $n$-hexane) and the aldehyde ( 2.0 mmol ) were added by syringe to a solution of chiral $1,2,3,4$-tetrahydro- $\beta$-carboline ( 0.20 mmol ) in dry toluene ( 8 ml ) under $\mathrm{N}_{2}$ protection at $0^{\circ} \mathrm{C}$. The reaction solution then warmed to room temperature and stirred for 48 or 96 h . After quenching with $5 \% \mathrm{HCl}$ aqueous solution, the mixture was extracted with ethyl acetate. The combined solution was dried over anhydrous $\mathrm{MgSO}_{4}$ and condensed under reduced pressure. The residue was purified by flash column chromatography (silica gel, $10 \%$ ethyl acetate in $n$-hexane) to give chiral 1-phenyl-1-propanol. The yields and enantioselectivities data were summarized in Tables 1-3.

### 3.1.4. Esterification of 1-cyclohexyl-1-propanol with ben-

 zyl chloride. Benzyl chloride ( 1.08 equiv.) and $\mathrm{NEt}_{3}$ ( 1.5 equiv.) were added to a solution of 1-cyclohexyl-1propanol ( $57 \mathrm{mg}, 0.4 \mathrm{mmol}$ ), dichloromethane ( 10 ml ) and catalytic quantity of DMAP in room temperature. After 48 h , the solution was filtered and the solvent was evaporated under reduced pressure. The residue was purified by flash column chromatography (silica gel) using ethyl acetate and hexane (1:25) to give the corresponding ester ( $84 \mathrm{mg}, 78.9$ yield).
