China

[^0]Introduction. - In our previous papers [1][2], 20 tetracyclic ent-kaurane diterpenoids were reported from Isodon rubescens (Hemsl.) Hara. Our continuing search for biologically active principles from this plant, collected in two different prefectures of the Henan Province of China, has now led to the isolation of six new ent-abietane diterpenoids named rubescensins $\mathrm{I}-\mathrm{M}(\mathbf{1}-\mathbf{5})$ and $\mathrm{P}(\mathbf{6})$, together with two related acetonide derivatives ( $\mathbf{7}$ and $\mathbf{8}$ ). In this paper, we report the isolation and structural elucidation of these new compounds.

Results and Discussion. - Structure Elucidation. Rubescensin I (1), obtained as an amorphous powder, gave rise to a molecular-ion peak at $\mathrm{m} / \mathrm{z} 336.2315$ in the HR-EI mass spectrum, consistent with the molecular formula $\mathrm{C}_{20} \mathrm{H}_{32} \mathrm{O}_{4}$. Careful analysis of the ${ }^{1} \mathrm{H}$ - and ${ }^{13} \mathrm{C}$-NMR data (Table 1) indicated $\mathbf{1}$ to be an ent-abietanoid similar to laxiflorin O (9) reported from I. eriocalyx var. laxiflora [3]. Compound $\mathbf{1}$ was elucidated as $(3 \alpha, 14 \beta)$-ent-abieta- $7,15(17)$-diene-3,4,16,18-tetraol by extensive analysis of its 2D-NMR spectra, and by comparison of the 1D-NMR spectra of $\mathbf{1}$ and 9 .

In the ${ }^{13} \mathrm{C}-\mathrm{NMR}$ spectrum of $\mathbf{1}$, signals of two olefinic quaternary C -atoms ( $\delta 141.2$ and 152.8), an olefinic $\mathrm{CH}_{2}(110.8)$, an olefinic $\mathrm{CH}(124.3)$, two $\mathrm{O}-\mathrm{CH}_{2}(66.1,64.6)$, five $\mathrm{CH}_{2}(38.1,27.9,25.7,23.9,23.4)$, two $\mathrm{O}-\mathrm{CH}(74.8,74.1)$, three $\mathrm{CH}(48.5,47.6$, 43.0 ), two nonoxygenated quaternary C -atoms (43.3, 35.1), and two Me groups (13.0, 15.9) were present. Thus, compound $\mathbf{1}$ was lacking one nonoxygenated quaternary Catom relative to the classical ent-kaurane skeleton, suggesting $\mathbf{1}$ to be a tricylic diterpenoid. Comparison of the ${ }^{1} \mathrm{H}$ - and ${ }^{13} \mathrm{C}$-NMR spectra of $\mathbf{1}$ and the known tricylic ent-abietanoid laxiflorin $\mathrm{O}(9)$ [3] revealed great similarities, except for one more OH group at $\mathrm{C}(14)$ of $\mathbf{1}$. Thus, $\mathbf{1}$ can be regarded as an ent-abietane diterpenoid corresponding to 14-hydroxylaxiflorin $O$. This was further supported by positive $[\alpha]_{D}$ values for $\mathbf{1}$ and 9 .

5

The above assignment was also corroborated by HMBC experiments (Fig. 1, a). The $\mathrm{CH}_{2}(17)=\mathrm{C}(15)$ moiety was confirmed by correlations of $\mathrm{CH}_{2}(17)$ ( $\delta 5.57$ and 5.28 ) with $\mathrm{C}(13)(\delta 47.6)$ and $\mathrm{C}(16)(\delta 64.6)$. The other $\mathrm{C}=\mathrm{C}$ bond was assigned to $\mathrm{C}(7)$ and $\mathrm{C}(8)$ on the ground of the observed HMBC correlation of $\mathrm{H}-\mathrm{C}(7)$ at $\delta_{\mathrm{H}} 5.66$ with $\mathrm{C}(5)$ at $\delta_{\mathrm{C}} 43.0$ and $\mathrm{C}(9)$ at $\delta_{\mathrm{C}} 48.5$. Due to the presence of the HMBC correlations of $\mathrm{H}-\mathrm{C}(3)$ with $\mathrm{C}(1), \mathrm{C}(5)$, and $\mathrm{C}(18)$, of $\mathrm{H}-\mathrm{C}(14)$ with $\mathrm{C}(7), \mathrm{C}(9)$, and $\mathrm{C}(15)$, of $\mathrm{CH}_{2}(16)$ with $\mathrm{C}(13)$ and $\mathrm{C}(17)$, and of $\mathrm{CH}_{2}(18)$ with $\mathrm{C}(3), \mathrm{C}(5)$, and $\mathrm{C}(19)$, the four OH groups were placed at $\mathrm{C}(3), \mathrm{C}(14), \mathrm{C}(16)$, and $\mathrm{C}(18)$, respectively (Table 1 and Fig. 1, a).

The relative configuration of $\mathbf{1}$ was derived by a ROESY experiment (Fig. 1,b). The $\alpha$-orientation of the $3-\mathrm{OH}$ and the $\beta$-orientation of the $14-\mathrm{OH}$ groups were apparent

Table 1. ${ }^{1} \mathrm{H}$ - and/or ${ }^{13} \mathrm{C}$-NMR Data of Compounds 1, 2, 7, and 8. 400 and 100 MHz , resp.; $\mathrm{C}_{5} \mathrm{D}_{5} \mathrm{~N} ; \delta$ in ppm, $J$ in Hz. Asterisks (*) mark overlapping signals.

Fig. 1. Key HMBC $(\mathrm{H} \rightarrow \mathrm{C})$ and ROESY correlations observed in $\mathbf{1}$
from the ROEs of $\mathrm{H}_{\beta}-\mathrm{C}(3)$ with both $\mathrm{H}_{\beta}-\mathrm{C}(5)$ and $\mathrm{CH}_{2}(18)$, and of $\mathrm{H}_{\alpha}-\mathrm{C}(14)$ with both $\mathrm{H}_{\alpha}-\mathrm{C}(13)$ and $\mathrm{H}-\mathrm{C}(7)$.

Compound 1 showed an unprecedented color change on TLC plates $\left(\mathrm{SiO}_{2}\right)$ from green to red to purple to blue when being baked at $200^{\circ}$ after dipping in $10 \%$ ethanolic $\mathrm{H}_{2} \mathrm{SO}_{4}$. So did rubescensin $J(2)$, having the molecular formula $\mathrm{C}_{20} \mathrm{H}_{30} \mathrm{O}_{3}$, as determined by HR-EI-MS ( $\mathrm{m} / \mathrm{z} 318.2193$; calc. 318.2195 ). Comparison of the ${ }^{1} \mathrm{H}-,{ }^{13} \mathrm{C}$-, and DEPTNMR data of $\mathbf{2}$ and $\mathbf{1}$ revealed that $\mathbf{2}$ was also an ent-abietanoid, differing from $\mathbf{1}$ only at $\mathrm{C}(14)$ and $\mathrm{C}(16)$. The clear HMBCs correlations between $\mathrm{H}-\mathrm{C}(14)\left(\delta_{\mathrm{H}} 4.18\right)$ and $\mathrm{C}(16)\left(\delta_{\mathrm{C}} 69.4\right)$, and between $\mathrm{CH}_{2}(16)\left(\delta_{\mathrm{H}} 4.55\right.$ and 4.26$)$ and $\mathrm{C}(14)$ indicated the presence of an O-bridge between $\mathrm{C}(14)$ and $\mathrm{C}(16)$, causing significant downfield
chemical shifts of $\mathrm{C}(14)\left(\delta_{\mathrm{C}} 83.4\right)$ and $\mathrm{C}(16)\left(\delta_{\mathrm{C}} 69.4\right)$. This was consistent with a molecular weight being 18 amu lower than that of $\mathbf{1}$ (condensation of $\mathrm{C}(14)-\mathrm{OH}$ and $\mathrm{C}(16)-\mathrm{OH}$ under loss of $\left.\mathrm{H}_{2} \mathrm{O}\right)$. Thus, $\mathbf{2}$ was elucidated as ( $3 \alpha$ )-14,16-epoxy-ent-abieta-7,15(17)-diene-3,18-diol.

Rubescensin K (3) was also an ent-abietanoid, as indicated by the same characteristic color changes in the TLC test. It exhibited an odd molecular-ion peak at $\mathrm{m} / \mathrm{z} 429$ in the EI mass spectrum, and an $[M+1]^{+}$signal at $m / z 430$ in the FAB mass spectrum, suggesting that it might contain a N -atom. The HR-EI-MS data ( $M^{+}$signal at $\mathrm{m} / \mathrm{z}$ 429.2871) verified this assumption, giving rise to the molecular formula $\mathrm{C}_{26} \mathrm{H}_{39} \mathrm{NO}_{4}$. On the basis of careful analysis of the ${ }^{1} \mathrm{H}-$ - ${ }^{13} \mathrm{C}$-, and 2D-NMR data (Table 2), compound $\mathbf{3}$ was identified as $3 \alpha,(3 \alpha, 14 \beta)-3,18-\{[(1 S)-4$-(acetylamino)butane-1,1-diyl]dioxy $\}-14,16$ -epoxy-ent-abieta-7,15(17)-diene, and was named rubescensin K , which is the first N containing diterpenoid isolated from Isodon plants.

Table 2. ${ }^{1} \mathrm{H}$ - and ${ }^{13} \mathrm{C}$-NMR Data of Compounds 3, 4, and 6. 400 and 100 MHz , resp.; $\mathrm{C}_{5} \mathrm{D}_{5} \mathrm{~N}$; $\delta$ in ppm, $J$ in Hz . Asterisks (*) mark overlapping signals.

Examination of the ${ }^{1} \mathrm{H}$ - and ${ }^{13} \mathrm{C}$-NMR data of $\mathbf{3}$ revealed that the molecule consisted of two portions, one of which closely resembled 2, except for the downfieldshifted $\mathrm{C}(3)$ and $\mathrm{C}(18){ }^{13} \mathrm{C}$-NMR signals at $\delta_{\mathrm{C}} 85.0$ and 77.9 , respectively. The other portion contained one N - and six C -atoms, including one $\mathrm{Me}\left(\delta_{\mathrm{C}} 23.1\right)$, three $\mathrm{CH}_{2}$ (24.7, $32.8,39.6$ ), a $\mathrm{C}=\mathrm{O}$ group (169.8), and one highly oxygenated CH (102.6). The $\mathrm{CH}_{2}\left(4^{\prime}\right)$ group resonating at $\delta_{\mathrm{C}} 39.6$ and $\delta_{\mathrm{H}} 3.48(\mathrm{~m})$ was linked with an acetamide $\mathrm{NH}\left(\delta_{\mathrm{H}} 8.44\right)$, as deduced from a ${ }^{1} \mathrm{H},{ }^{1} \mathrm{H}$-COSY experiment, as well as from the HMBC correlations (Fig. 2) of both the $\mathrm{CH}_{2}\left(4^{\prime}\right)\left(\delta_{\mathrm{H}} 3.48\right)$ and a Me group ( $\delta_{\mathrm{H}} 1.99$ ) with the $\mathrm{C}=\mathrm{O} \mathrm{C}$-atom ( $\delta_{\mathrm{C}} 169.8$ ). $\mathrm{H}-\mathrm{C}\left(1^{\prime}\right)\left(\delta_{\mathrm{C}} 102.6 ; \delta_{\mathrm{H}} 4.67\right)$ was linked with $\mathrm{C}(3)$ and $\mathrm{C}(18)$ according to a HMBC experiment. In the ${ }^{1} \mathrm{H},{ }^{1} \mathrm{H}$-COSY spectrum, the overlapping $\mathrm{CH}_{2}\left(2^{\prime}\right)$ and $\mathrm{CH}_{2}\left(3^{\prime}\right)$ resonances ( $\delta_{\mathrm{H}} 1.90-1.78$ ) exhibited correlations with the H -atoms of $\mathrm{CH}\left(1^{\prime}\right)$ and $\mathrm{CH}_{2}\left(4^{\prime}\right)\left(\delta_{\mathrm{H}} 3.48\right)$, respectively, suggesting that $\mathrm{C}\left(1^{\prime}\right)$ to $\mathrm{C}\left(4^{\prime}\right)$ were anchored in a line, as confirmed by the HMBC experiment (Fig. 2). The $\mathrm{H}-\mathrm{C}\left(1^{\prime}\right) \mathrm{H}$-atom was involved in NOEs with $\mathrm{H}_{\beta}-\mathrm{C}(3)$ and $\mathrm{CH}_{2}(18)$, confirming $\beta$-configuration at $\mathrm{C}\left(1^{\prime}\right)$.

Fig. 2. Key HMBC $(\mathrm{H} \rightarrow \mathrm{C})$ correlations observed in $\mathbf{3}$
Rubescensin L(4), a white amorphous powder, gave rise to a molecular-ion peak at $\mathrm{m} / \mathrm{z} 480$ in the EI mass spectrum, in accord with the molecular formula $\mathrm{C}_{26} \mathrm{H}_{40} \mathrm{O}_{8}$, as determined by HR-EI-MS (480.2708 ( $M^{+}$; calc. 480.2723)). Analysis of the ${ }^{1} \mathrm{H}-$ and ${ }^{13} \mathrm{C}$-NMR data indicated that $\mathbf{4}$ was a glucoside of $\mathbf{2}$. The significant downfield shift of $\mathrm{C}(18)\left(\delta_{\mathrm{C}} 76.0\right)$ of $\mathbf{4}$, in combination with the ${ }^{1} \mathrm{H}$ - and ${ }^{13} \mathrm{C}-\mathrm{NMR}$ data and coupling patterns of the glucose moiety with reference data [4], suggested that a $\beta$-D-glucose unit was linked at $\mathrm{C}(18)$, which was confirmed by HMBCs correlations between $\mathrm{CH}_{2}(18)$ ( $\delta_{\mathrm{H}} 4.21$ and 3.53 ) and $\mathrm{C}\left(1^{\prime}\right)\left(\delta_{\mathrm{C}} 105.8\right)$, and between $\mathrm{H}-\mathrm{C}\left(1^{\prime}\right)\left(\delta_{\mathrm{H}} 4.84\right)$ and $\mathrm{C}(18)$. Therefore, $\mathbf{4}$ was established as the $18-O-\beta$-D-glycopyranoside of 2 .

Rubescensin M(5) was obtained as a white amorphous powder. FAB-MS exhibited an $[M+1]^{+}$peak at $m / z 683$, consistent with the molecular formula $\mathrm{C}_{40} \mathrm{H}_{58} \mathrm{O}_{9}$, as determined by both HR-FAB-MS and ${ }^{1} \mathrm{H}-$ and ${ }^{13} \mathrm{C}-\mathrm{NMR}$ (Table 3). Analysis of the spectral data, including 2D-NMR, indicated that 5 was composed of two diterpene moieties (partial structures 5a and 5b), as shown in Fig. 3. Thereby, based on NMR, 5a was identical with $\mathbf{2}$, and $\mathbf{5 b}$ was suggested to be a 7,20 -epoxy-ent-kaurane due to the characteristic signals of three nonoxygenated quaternary C -atoms $\left[\mathrm{C}\left(4^{\prime}\right), \mathrm{C}\left(8^{\prime}\right), \mathrm{C}\left(10^{\prime}\right)\right.$ at $\delta_{\mathrm{C}} 33.6,52.4,43.5$, resp.], two Me groups at quaternary C -atoms [ $\mathrm{C}\left(18^{\prime}\right)$ and $\mathrm{C}\left(19^{\prime}\right)$ at $\delta_{\mathrm{C}} 33.5$ and 22.3 , resp.], a hemiketal C -atom $\left[\mathrm{C}\left(7^{\prime}\right)\right.$ at $\delta_{\mathrm{C}}$ 101.5], and three nonoxygenated CH groups [ $\mathrm{C}\left(5^{\prime}\right), \mathrm{C}\left(9^{\prime}\right), \mathrm{C}\left(13^{\prime}\right)$ at $\delta_{\mathrm{C}} 56.7,45.0,46.4$, resp.]. Further comparison of the ${ }^{1} \mathrm{H}$ - and ${ }^{13} \mathrm{C}$-NMR data of $\mathbf{5 b}$ and rabdoternins B and F [5] [6], two known 7,20-epoxy-ent-kauranoids that had been isolated as well, suggested that $\mathbf{5 b}$ was
a $7 \alpha, 20$-epoxy-ent-kaur-16-ene-1,6,7,14,15-pentaol, strongly resembling rabdoternin B , except for the oxygenation pattern of $\mathrm{C}(20)$, and differing from rabdoternin F only at $\mathrm{C}(15)$. Furthermore, it was deduced that $\mathbf{5 a}$ and $\mathbf{5 b}$ were linked together by an oxy bridge between $\mathrm{C}(18)\left(\delta_{\mathrm{C}} 71.7\right)$ and $\mathrm{C}\left(20^{\prime}\right)\left(\delta_{\mathrm{C}} 101.8\right)$ on the basis of HMBC correlations between $\mathrm{H}-\mathrm{C}(20)$ and $\mathrm{C}(18)$, as well as between $\mathrm{CH}_{2}(18)$ and $\mathrm{C}\left(20^{\prime}\right)$ (Fig. 3).

Table 3. ${ }^{1} \mathrm{H}$ - and ${ }^{13} \mathrm{C}$-NMR Data of Compound $\mathbf{5}$. Note that $\mathbf{5 a}$ and $\mathbf{5 b}$ are ether-bridged fragment structures (see chemical formula). 400 and 100 MHz , resp.; $\mathrm{C}_{5} \mathrm{D}_{5} \mathrm{~N} ; \delta$ in ppm, $J$ in Hz. Asterisks (*) mark overlapping signals.

Fig. 3. Key HMBC $(\mathrm{H} \rightarrow \mathrm{C})$ correlations observed in $\mathbf{5}$

The relative configuration of $\mathbf{5}$ was confirmed by a ROESY experiments (Fig. 4). The orientations of the OH groups at $\mathrm{C}\left(1^{\prime}\right), \mathrm{C}\left(6^{\prime}\right)$, and $\mathrm{C}\left(14^{\prime}\right)$ were shown to be $\alpha, \beta$, and $\beta$, respectively, as deduced from the NOEs between $\mathrm{H}_{\beta}-\mathrm{C}\left(1^{\prime}\right)\left(\delta_{\mathrm{H}} 3.66\right)$ and $\mathrm{H}_{\beta}-\mathrm{C}\left(5^{\prime}\right)\left(\delta_{\mathrm{H}} 1.62\right)$, and between $\mathrm{H}_{\beta}-\mathrm{C}\left(9^{\prime}\right)\left(\delta_{\mathrm{H}} 2.89\right)$ and $\mathrm{H}_{\alpha}-\mathrm{C}\left(6^{\prime}\right)\left(\delta_{\mathrm{H}} 4.11\right)$ and $\operatorname{Me}\left(19^{\prime}\right)\left(\delta_{\mathrm{H}} 1.05\right)$, as well as between $\mathrm{H}_{\alpha}-\mathrm{C}\left(14^{\prime}\right)\left(\delta_{\mathrm{H}} 5.16\right)$ and $\mathrm{H}_{a}-\mathrm{C}\left(11^{\prime}\right)\left(\delta_{\mathrm{H}} 2.67\right)$, respectively. However, there was no NOE for $\mathrm{H}-\mathrm{C}\left(15^{\prime}\right)$, suggesting an $\alpha$-orientation, which was confirmed by the steric effect between $\mathrm{H}_{\beta}-\mathrm{C}\left(9^{\prime}\right)$ and $\mathrm{HO}-\mathrm{C}\left(15^{\prime}\right)$ indicated by an upfield shift of $\mathrm{C}\left(9^{\prime}\right)\left(\delta_{\mathrm{C}} 45.0\right)$. Finally, the relative $(S)$-configuration at $\mathrm{C}\left(20^{\prime}\right)$ was determined by the key NOE between $\mathrm{H}-\mathrm{C}\left(20^{\prime}\right)$ and $\mathrm{Me}\left(19^{\prime}\right)$. There were also NOEs between $\mathrm{H}-\mathrm{C}\left(20^{\prime}\right)$ and $\mathrm{H}_{\beta}-\mathrm{C}(3)$, and between $\mathrm{H}-\mathrm{C}\left(20^{\prime}\right)$ and $\mathrm{CH}_{2}(18)$, confirming the linkage between the two moieties of 5 .

Fig. 4. Key ROESY correlations observed in $\mathbf{5}$

Rubescensin P (6), an amorphous powder, had the same molecular formula $\left(\mathrm{C}_{20} \mathrm{H}_{32} \mathrm{O}_{4}\right)$ as $\mathbf{1}$, as revealed by HR-EI-MS. Comparison of the ${ }^{13} \mathrm{C}$-NMR data of $\mathbf{6}$ (Table 2) and $\mathbf{1}$ (Table 1) indicated that they both had two $\mathrm{OCH}_{2}$, two OCH , two olefinic quaternary C -atoms, an olefinic CH , and an olefinic $\mathrm{CH}_{2}$, with differences in rings B and C , which were detailed by HMBC correlations between $\mathrm{H}-\mathrm{C}(14)\left(\delta_{\mathrm{H}} 5.89\right)$ and both $\mathrm{C}(15)\left(\delta_{\mathrm{C}} 155.1\right)$ and $\mathrm{C}(9)\left(\delta_{\mathrm{C}} 46.5\right)$ (Fig. 5), suggesting the presence of a $\mathrm{C}=\mathrm{C}$ bond between $\mathrm{C}(8)\left(\delta_{\mathrm{C}} 141.8\right)$ and $\mathrm{C}(14)\left(\delta_{\mathrm{C}} 128.7\right)$. The $\beta$-orientation of $\mathrm{HO}-\mathrm{C}(7)$ was indicated by the HMBC correlations between $\mathrm{H}_{\alpha}-\mathrm{C}(7)$ and both $\mathrm{C}(5)$ and $\mathrm{C}(9)$, and by the NOE of $\mathrm{H}_{\alpha}-\mathrm{C}(7)$ and $\mathrm{H}-\mathrm{C}(14)$. Thus, $\mathbf{6}$ was determined to be ( $3 \alpha, 7 \beta$ )-ent-abieta-8(14),15(17)-diene-3,7,16,18-tetraol.

Fig. 5. Key HMBC $(\mathrm{H} \rightarrow \mathrm{C})$ correlations observed in $\mathbf{6}$

The ${ }^{13} \mathrm{C}$-NMR spectrum of $\mathbf{7}$ closely resembled that of $\mathbf{1}$, except for three extra Catom signals at $\delta_{\mathrm{C}} 99.0,30.2$, and 19.4 , suggesting that 7 was an acetonide derivative of 1. The acetonide group was located between $C(3)$ and $C(18)$, as indicated by HMBC correlations between both $\mathrm{H}-\mathrm{C}(3)\left(\delta_{\mathrm{H}} 3.50\right)$ and $\mathrm{CH}_{2}(18)\left(\delta_{\mathrm{H}} 3.48\right.$ and 3.26) with the quaternary C -atom ( $\delta_{\mathrm{C}} 99.0$ ) of the $\mathrm{Me}_{2} \mathrm{C}$ group. The relative configurations at $\mathrm{C}(3)$ and $C(14)$ were assigned by the NOEs in the ROESY spectrum of 7 . Therefore, 7 was identified as $(3 \alpha, 14 \beta)$-3,18-[(1-methylethane-1,1-diyl)dioxy]-ent-abieta-7,15(17)-di-ene-14,16-diol; in the same way, compound $\mathbf{8}^{1}$ ) was elucidated as the acetonide of $\mathbf{2}$.

The isolation of ent-abietanoids from an Isodon plant, a genus notable as a rich source of tetracyclic ent-kauranoids [8], may suggest a potential biogenesis path from ent-kaurane to ent-abietane, because these ent-abietanoids, without the key $\mathrm{H}_{\alpha}-\mathrm{C}(8)$ of the ent-abietane skeleton, could also be regarded as 8,15 -seco-ent-kauranoids.

Cytotoxicity. The new compounds $\mathbf{1 - 8}$ were tested for their cytotoxity against human-tumor K562 cells by a method previously described [7]. Only compound $\mathbf{3}$ exhibited a significant inhibitory effect, with an $I C_{50}$ value of $0.49 \mu \mathrm{~g} / \mathrm{ml}$, which is in the range of cisplatin $(1.44 \mu \mathrm{~g} / \mathrm{ml})$.

## Experimental Part

General. Optical rotations: JASCO DIP-370 digital polarimeter. UV Spectra: Shimadzu UV-210A spectrometer; $\lambda_{\max }$ in nm, $(\log \varepsilon)$. IR Spectra: Bio-Rad FtS-135 spectrometer; KBr pellets; in $\mathrm{cm}^{-1}$. 1D- and 2DNMR Spectra: Bruker $A M-400$ and $D R X-500$ spectrometers; in $\mathrm{C}_{5} \mathrm{D}_{5} \mathrm{~N} ; \delta$ in ppm rel. to $\mathrm{SiMe}_{4}$ as internal standard, $J$ in Hz. Mass spectra: $V G$ Autospec-3000 spectrometer ( 70 eV for EI); in $\mathrm{m} / \mathrm{z}$ (rel. \%).

Plant Material. Plants of Isodon rubescens were collected in the Jiyuan and Hebi Prefectures in August 1999 and August 2000, resp., Henan Province of China. They were identified by Prof. Zhong-Wen Lin. Voucher specimens (KIB-99-10-13 Lin and KIB-2000-8 Lin) were deposited in the Herbarium of the Department of Taxonomy, Kunming Institute of Botany, Chinese Academy of Science.

Extraction and Isolation. a) Plant Material from the Jiyuan Prefecture. The air-dried leaves ( 13 kg ) of $I$. rubescens from the Jiyuan Prefecture were extracted with $70 \%$ aq. acetone at r.t. overnight ( $3 \times$ ), and the extract was filtered. The filtrate was evaporated, and the resulting residue was partitioned between $\mathrm{H}_{2} \mathrm{O}$ and AcOEt. The AcOEt fraction ( 424 g of dry extract) was purified by column chromatography (CC) ( 3 kg of $\mathrm{SiO}_{2}$ (100-200 mesh); $\mathrm{CHCl}_{3} /$ acetone $1: 0 \rightarrow 0: 1$ ), affording Fractions I-IX. After repeated CC $\left(\mathrm{SiO}_{2} ;\right.$ gradient mixtures of $\left.\mathrm{CHCl}_{3} / \mathrm{MeOH}\right)$, Fraction VII afforded $\mathbf{1}(150 \mathrm{mg}), \mathbf{7}(14 \mathrm{mg})$, and $\mathbf{2}(110 \mathrm{mg})$. In the same way, $\mathbf{3}$ ( 8 mg ), $\mathbf{4}(5 \mathrm{mg})$, and $5(6 \mathrm{mg})$ were isolated from Fraction VIII.
b) Plant Material from the Hebi Prefecture. The air-dried leaves $(10 \mathrm{~kg})$ of $I$. rubescens from the Hebi Prefecture were extracted with $70 \%$ aq. acetone at r.t. overnight ( $3 \times$ ), and the extract was filtered. The filtrate was evaporated, and the resulting residue was partitioned between $\mathrm{H}_{2} \mathrm{O}$ and AcOEt. The AcOEt fraction ( 400 g of dry extract) was purified by $\mathrm{CC}\left(\mathrm{SiO}_{2} ; \mathrm{CHCl}_{3} ; \mathrm{CHCl}_{3} /\right.$ acetone $9: 1,8: 2,7: 3,6: 4$; acetone $)$ to afford Fractions I-VI. Compounds $\mathbf{1}(50 \mathrm{mg}), \mathbf{7}(6 \mathrm{mg}), \mathbf{2}(80 \mathrm{mg})$, and $\mathbf{8}(20 \mathrm{mg})$ were isolated from Fraction $V$, and compounds $\mathbf{4}(20 \mathrm{mg})$ and $\mathbf{6}(23 \mathrm{mg})$ were obtained from Fraction VI by repeated CC $\left(\mathrm{SiO}_{2}\right.$; gradient mixtures of $\left.\mathrm{CHCl}_{3} / \mathrm{MeOH}\right)$, followed by repeated prep. TLC $\left(\mathrm{SiO}_{2} ; \mathrm{CHCl}_{3} / \mathrm{MeOH} 10: 1\right)$.
(3 $3,14 \beta$ )-ent-Abieta-7,15(17)-diene-3,14,16,18-tetraol (Rubescensin I; 1). [^0]:    Six new ent-abietane diterpenoids, rubescensins I-M(1-5) and P(6), along with two related acetonide derivatives ( $\mathbf{7}$ and $\mathbf{8}$ ), were isolated from Isodon rubescens. Their structures were elucidated by detailed spectroscopic analysis. Compound $\mathbf{5}$ is the first N -containing diterpenoid from the genus Isodon, exhibiting notable cytotoxicity against human tumor K562 cells.
